### 3 Introduction

Software Patching over the Air (SPotA) service exposes a control point to allow a peer device to initiate software patching over the air. SPotA defines 2 roles:

- The “SPOTA Initiator” is the endpoint which transmits the patch payload.
- The “SPOTA Receiver” is the endpoint which receives and applies the patch payload.

Patching code is sent by the Initiator using the Bluetooth Smart link. Receiver stores the patch into the internal RAM or an external non-volatile memory and then applies the patch. Software Patching over the Air (SPotA) is instantiated as a Primary Service. There is only one instance of this service on a device.

The SPotA service can be also used by the Initiator to update the entire image of the Receiver. In this case the Initiator uses the SPotA service but instead of a single patch the entire image is set in multiple patches. This specific mode of SPOTA service is referred to as Software Update over the Air (SUotA). More details about SUotA are given at chapter 0.

SPOTA service is a Dialog Semiconductor proprietary service and is described in detail in [1].

### 4 Software Description

The DA14580 Software Development Kit (SDK) [2] includes a Keil project which implements the Receiver role (SPOTAR):

```
dk_apps\keil_projects\proximity\reporter_fh\fh_proxr_sdk.uvproj
```

The SPOTAR profile is implemented in the following files:

```
dk_apps\src\ip\ble\hl\src\profiles\spotar\spotar.c  
dk_apps\src\ip\ble\hl\src\profiles\spotar\spotar_task.c
```

The SPOTAR application source code is located in the following directory:

```
dk_apps\src\modules\app\src\app_profiles\spotar
```

### 5 Getting Started

This section describes how to set up the application software and the DA14580 Development board to run the SPOTAR application. It is assumed that the user is familiar with using the DA14580 Development Kit (SDK) [4].

#### STEP 1: Starting SPOTAR device

On a Windows machine, start the Keil environment and open the project:

```
dk_apps\keil_projects\proximity\reporter_fh\fh_proxr_sdk.uvproj
```

Build this project (F7) and follow the steps in the user guide [4] to load the executable in the DK and run the executable.

#### STEP 2: Running Connection Manager (for DA14580 USB dongle)

DA14580 USB Dongle will be used as the SPOTAI device. When the dongle is inserted in a Windows machine (e.g. laptop) a J-Link device should be discovered in Windows devices and printers. In J-Link's properties, a JLink CDC UART Port is displayed. The user must keep the virtual COM port number to configure the Connection Manager application.

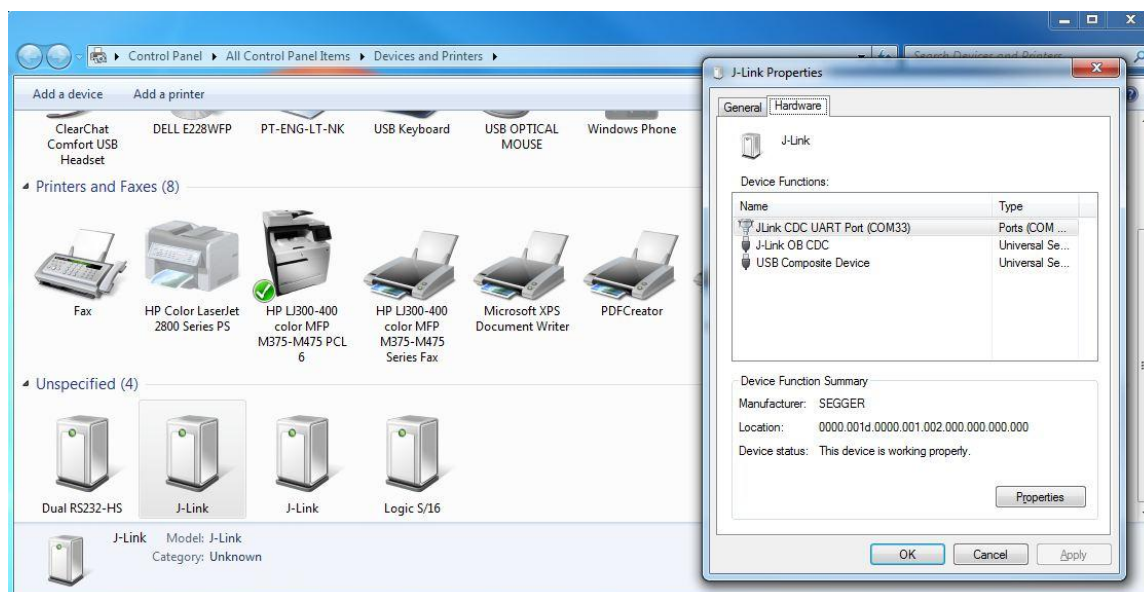

Figure 1: J-Link device discovered

Start the Connection Manager software, on the right pane set the com port to the com port of the JLink CDC UART Port and click the “Boot as Central” button.

### STEP 3: Connecting SPOTAL device to the SPOTAR device

In the left pane of the Connection Manager software, click the “Scan” button to discover the SPOTAR device that should be advertising at this point.

Figure 2: Central Device has discovered advertising device

If the SPOTAR device is discovered, its public address will appear in the “Link Control” section as seen in Figure 2. At this point, a connection to the SPOTAR device can be established by clicking the “Establish Link” button.

### STEP 4: Reading the SPOTAR service database

After the connection is established successfully, the entire attribute database is displayed on the bottom pane of the Connection Manager software. To understand the characteristics of the profile the application note [1] needs to be studied carefully.

### STEP 5: Configuring the SPOTAR device

At this point it is assumed that the user is familiar with the profile and its characteristics. Note that the SPotA service is a Dialog Semiconductor proprietary service. The Bluetooth SIG has assigned a 16 bit UUID for Dialog SPOTAR service which is: **0xFE5**. The UUIDs of the characteristics of the profile are proprietary 128 bits UUIDs as defined in [1].

0x0019	2800	-	Primary Service Definition
0x001A	2803	-	Characteristic Declaration
0x001B	8082CAA841A6402191C656F9B954CC34	Read, Write	User-defined UUID
0x001C	2803	-	Characteristic Declaration
0x001D	724249F05EC34B5F880442345AF08651	Read, Write	User-defined UUID
0x001E	2803	-	Characteristic Declaration
0x001F	6C53DB2547A145FEA0227C92FB334FD4	Read	User-defined UUID
0x0020	2803	-	Characteristic Declaration
0x0021	9D84B9A3000C49D89183855B673FDA31	Read, Write	User-defined UUID
0x0022	2803	-	Characteristic Declaration
0x0023	457871E8D5164CA1911657D0B17B9CB2	Read, Write	User-defined UUID
0x0024	2803	-	Characteristic Declaration
0x0025	5F78DF94798C46F5990AB3EB6A065C88	Read, Notify	User-defined UUID
0x0026	2902	-	Client Characteristic Configuration

**Figure 3: SPOTAR attribute table**

Figure 3 shows the SPOTAR service part of the attribute database. The Characteristic UUIDs in this implementation are as follows:

```

8082caa841a6402191c656f9b954cc34 => SPOTA_MEM_DEV_UUID
724249f05ec34b5f880442345af08651 => SPOTA_GPIO_MAP_UUID
6c53db2547a145fea0227c92fb334fd4 => SPOTA_MEM_INFO_UUID
9d84b9a3000c49d89183855b673fda31 => SPOTA_PATCH_LEN_UUID
457871e8d5164ca1911657d0b17b9cb2 => SPOTA_PATCH_DATA_UUID
5f78df94798c46f5990ab3eb6a065c88 => SPOTA_SERV_STATUS_UUID

```

The example that is described below refers to a software patch of 11 words that will be stored in to an external SPI Flash memory [5].

### Enable SPOTAR status notifications

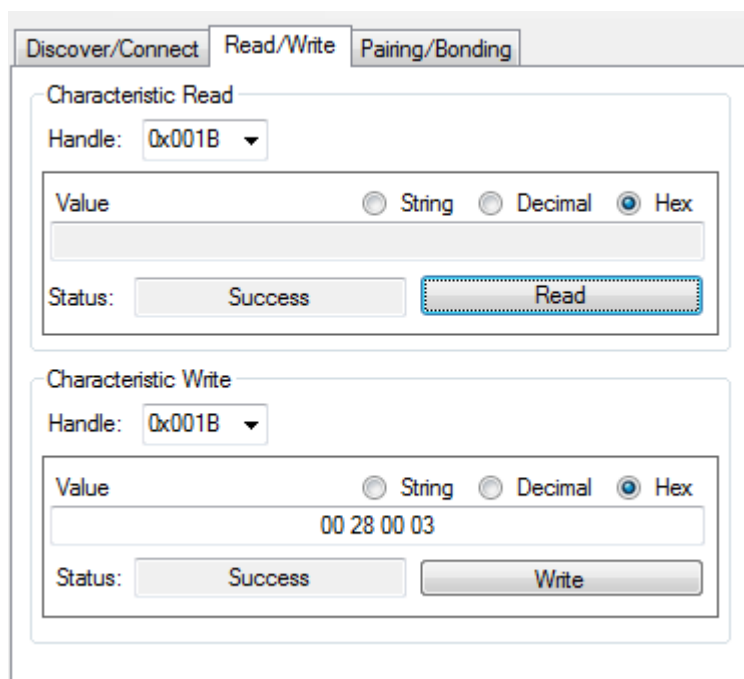

This is an optional step. If the Initiator, the client device in this case (Connection Manager & USB dongle), wishes to receive SPOTAR status notifications, it should enable the notifications first. To achieve this, it must write the value 0x0001 to the client characteristic configuration descriptor for the SPOTA\_SERV\_STATUS characteristic. The handle for the client characteristic configuration descriptor immediately follows the characteristic value's handle. Therefore, the value 0x0001 must be written to handle 0x0026. In the lowest pane of the Connection manager software, click on the handle 0x0026 to select the characteristic, select "Hex" as the format of the value and then in the "Characteristic Write" section, enter "01 00" in the "Value" field (note that the LSB is entered first, and the MSB is entered last). Click the "Write" button. The status box will display "Success", indicating that the write was successful.

### Set memory base address and memory device

Firstly, in order for the Initiator to indicate to the Receiver that wishes to start the SPotA service, it has to write the SPOTA\_MEM\_DEV characteristic value.

In this example, the Initiator wishes to write the patch into external SPI Flash memory at address 0x002800. In the Connection Manager software click on the "Read/Write" tab. Then, in the "Characteristic Write" section, select the 0x001B handle (which is the handle of SPOTA\_MEM\_DEV) and in the value field enter: "00 28 00 03", as shown in Figure 4, and click the "Write" button. Note that "Hex" has been selected as the format of the value.

To test if the value has been written correctly, the value of the characteristic can be read in the "Characteristic Read" section. Also the status box will display "Success", indicating that the write was successful.

The screenshot shows a software interface with three tabs: 'Discover/Connect', 'Read/Write', and 'Pairing/Bonding'. The 'Read/Write' tab is active. It contains two sections: 'Characteristic Read' and 'Characteristic Write'. In the 'Characteristic Write' section, the 'Handle' is set to '0x001B'. The 'Value' field is set to '00 28 00 03' in hexadecimal format. The 'Status' is 'Success' and the 'Write' button is highlighted.

Figure 4: Write Characteristic value example

### Set GPIO mapping for SPI FLASH

The next characteristic that should be set by the Initiator is SPOTA\_GPIO\_MAP. In the “Characteristic Write” section, select the 0x001D handle and in the value field enter: “00 03 06 05”

This value means: 00:P0\_0/CLK, 03:P0\_3/CS, 06:P0\_6/MOSI, 05:P0\_5/MISO.

### Read patch information from memory

At this point, the Initiator can read the overall patch length and actual number of patches from the memory if there are any patches written in the past. In the “Characteristic Read” section, select the 0x001F handle to read SPOTA\_MEM\_INFO characteristic value.

### Set overall patch data length

At this point, the Initiator shall set the length of the patch data that will be sent. Note that the length represents byte count. For our example the overall patch length is 44 bytes (or 11 words). In the “Characteristic Write” section, select the 0x0021 handle and in the value field enter: “2c 00” and click the “Write” button to write the SPOTA\_PATCH\_LEN characteristic value. Please note that “Hex” shall be selected as the format of the value.

### Send the patch data

The next characteristic that should be set by the Initiator is SPOTA\_PATCH\_DATA. In this example, the patch that the Initiator wishes to send is three patch entries of **11 words total length**. Refer to [6] and [7] to understand how to construct patch headers. Below, the data of the patch are listed and a short explanation is given:

- Block copy of 7 words at start address 0x7000 (offset from 0x20000000 system RAM base).  
 0x00077000 // 1<sup>st</sup> Patch header: Block copy of 7 words at start address 0x7000.  
 0x12345678 // 1<sup>st</sup> of the 7 words.  
 0xAAAAAAAA // 2<sup>nd</sup> of the 7 words.  
 0xBBBBBBBB // and so on...  
 0xCCCCCCCC

0xDDDDDDDD

0xEEEEEEEE

0xFFFFFFFF // last word of the 1<sup>st</sup> patch (7<sup>th</sup> word).

- b. Dummy patch entry

0x00007000 // **2<sup>nd</sup> Patch header:** Dummy patch header.

- c. Block copy of 1 word, update memory 0x701c

0x0001701C // **3<sup>rd</sup> Patch header:** Block copy of 1 word at 0x701c.

0xCAFEDEAD // the word to be copied.

Now that the patch has been constructed, the Initiator needs to write all these words in chunks of 20 bytes (max data MTU that is supported for a single characteristic write) in the “Characteristic Write” section. So the following byte sequence should be written to the handle 0x0023:

- i. 00 70 07 00 78 56 34 12 AA AA AA AA BB BB BB BB CC CC CC CC
- ii. DD DD DD DD EE EE EE EE FF FF FF FF 00 70 00 00 1C 70 01 00
- iii. AD DE FE CA

As illustrated in this example, the patch data shall be sent in the following order: the first patch header first and least significant byte first.

NOTE: At this point the Initiator can read the overall patch length and actual number of patches from the memory. In the “Characteristic Read” section, select the 0x001F handle to read SPOTA\_MEM\_INFO characteristic value. The following value should be displayed: “0B 00 03 00”, meaning that 3 patches are already written in the memory and the overall length is 11, 32-bit words.

### Execute the software patch

Assuming that the patch has been received correctly by the SPOTAR device, then when the SPOTAR device wakes up from sleep or after reset, the patch will be applied. In this example, after the patch has been applied, the system RAM memory area at address 0x20007000 will have the values shown in Figure 5.

Memory 1	
Address:	0x20007000
0x20007000:	FFFFFFFF EEEEEEEE DDDDDDDD CCCCCCCC BBBB BBBB AAAAAAAA 12345678 CAFEDEAD 93C17F78
0x20007024:	6155143E D9C3E935 CEDBD571 3A3708DD 52291192 0517EF5C 3C7F3D54 8B302A96 216E4CF8

Figure 5: Memory area after applying patch

## 6 SPOTA Initiator Host application

The DA14580 Software Development Kit (SDK) [2] also includes a Windows Visual C++ project which implements the Initiator application (SPOTAL). A command line driven console application has been developed and can be also used to test the SPOTA implementation. The source code can be found under the following directory:

*host\_apps\windows\spota\initiator*

This application, in conjunction with the DA14580 USB Dongle, implements an external processor solution of SPOTAL. Therefore, to run this application from a Windows console it is assumed that:

- the DA14580 USB Dongle is already installed and can be used by the Windows machine.
- the DA14580 USB Dongle has been loaded with a firmware in external processor configuration. A suitable firmware can be found in DA14580 SDK: *dk\_apps\keil\_projects\proximity\monitor\_fe*

SPOTAL application command description:

**host\_spotai** <com port number> <bdaddr> <.bin file> <mem\_dev\_opts>

**<com port number>** = the com port number for the USB Dongle DA14580 for the SPOTA initiator. E.g. 16 for COM16.

**<bdaddr>** = the BD address of the target SPOTA receiver device. E.g. 25:07:19:77:23:01.

**<.bin file>** = the binary file containing the patch data. The file is expected to store the words in LE order.

E.g. if the patch includes 1 patch entry with the following 2 words:

0x0001701C

0xCAFEDEAD

then the binary file shall contain the following bytes:

1C 70 01 00 AD DE FE CA

**<mem\_dev\_opts>** = sysram | retram | i2c <i2c\_dev\_opts> | spi <spi\_dev\_opts>

**<i2c\_dev\_opts>** = <patch base addr> <I2C device addr> <SCL gpio> <SDA gpio>

**<spi\_dev\_opts>** = <patch base addr> <MISO gpio> <MOSI gpio> <CS gpio> <SCK gpio>

**<patch base addr>** = the patch base address in the target memory device. It is a HEX value, e.g. A000

**<I2C device addr>** = the I2C slave address for the I2C memory device. It is an 8-bit HEX value, e.g. 0B.

**<XXX gpio>** = the name of the gpio that is assigned for the XXX function, e.g. P2\_2

Command line examples:

- **SYSRAM:**

host\_spotai 56 25:07:19:77:23:01 patch.bin sysram

- **RETRAM:**

host\_spotai 56 25:07:19:77:23:01 patch.bin retram

- **I2C:**

host\_spotai 56 25:07:19:77:23:01 patch.bin i2c 800 50 P0\_2 P0\_3

- **SPI:**

host\_spotai 56 25:07:19:77:23:01 patch.bin spi 2800 P0\_5 P0\_6 P0\_3 P0\_0

## 7 Software Update over the Air (SUotA)

The SPotA service can be also used by the Initiator to update the entire image of the Receiver. In this case the Initiator uses the SPotA service but instead of a single patch the entire image is set in multiple patches. These patches are referred to as image blocks. In this chapter a description will be given of how to use the SPotA service to send an image to the Receiver instead of a single patch.

A demo SUOTA Receiver application is part of the DA14580 SDK software and it is implemented in the following project:

*dk\_apps\keil\_projects\proximity\reporter\_fh\fh\_proxr\_sdk.uvproj*

The application source code is located in the following directory:

*dk\_apps\src\modules\applsrc\app\_profiles\spotar*

### 7.1 SUOTA basic operation

The basic operational steps of a SUOTA session are described below. For more profile specific information, refer to [1]:

1. The Initiator scans for a device which supports SPOTA service and establishes a connection.
2. The Initiator then writes the SPOTA\_MEM\_DEV characteristic value to indicate that it wishes to start a SUOTA session and also sets the image bank to be updated (1<sup>st</sup>, 2<sup>nd</sup> or older) [8].
3. The Initiator then writes the SPOTA\_GPIO\_MAP to configure the Receiver to set up the SPI or the I2C pads, depending on whether the external memory is FLASH or EEPROM, respectively.
4. The Initiator then writes the SPOTA\_PATCH\_LEN characteristic to specify the block length. This tells the Receiver, that the image will be sent in data blocks of the specified length. The Receiver has to have an available buffer space in SRAM in order to store the block data, otherwise responds with an error code.
5. The Initiator starts sending the Image data using the SPOTA\_PATCH\_DATA characteristic. On the Receiver side, received packets are stored into SRAM. After the first 64 bytes have been received, the Receiver validates the header of the new image and if it is correct, finds the start address of the image bank that shall be updated (1<sup>st</sup>, 2<sup>nd</sup> or older depending on the Initiator preference), otherwise returns an error code to the Initiator.
6. The Receiver counts the received image data length. When the length of the data received is equal to the Initiator defined block length (set in step 4), the image data are stored into the external non-volatile memory (FLASH/EEPROM device)
7. The steps 5 and 6 are repeated until the entire image is sent. The Initiator sends the last packet with an overall checksum. Note that SPOTA\_PATCH\_LEN might be needed to be set again prior to sending the last block if the length of the last block is different (this happens when the image size is not an exact multiple of the block length, then the last block will have a different length value).
8. The Receiver validates the checksum, sets the "validflag" in the image header and restarts the system. Note that the non-volatile memory needs to have a few pre-programmed headers to meet the needs of the dual image bootloader. Refer to [8] to understand the memory map of the non-volatile memory.
9. A dual image bootloader [8] detects and executes the active (last updated and valid) image.

## 7.2 SUOTA Initiator Host Application

The DA14580 Software Development Kit also includes a Windows Visual C++ project which implements the Initiator application (SUOTAI). A command line driven console application has been developed and can be also used to test the SUOTA implementation. The source code can be found under the following directory:

*host\_apps\windows\suotainitiator*

This application, in conjunction with the DA14580 USB Dongle, implements an external processor solution of SUOTAI. Therefore, to run this application from a Windows console it is assumed that:

- the DA14580 USB Dongle is already installed and can be used by the Windows machine.

the DA14580 USB Dongle has been loaded with a firmware in external processor configuration. A suitable firmware can be found in DA14580 SDK: *dk\_apps\keil\_projects\proximity\monitor\_feSUOTAI* application command description:

**host\_suotai <com port number> <bdaddr> <.bin file> <mem\_dev\_opts>**

**<com port number>** = the com port number for the full embedded DA14580 for the Initiator. E.g. 16 for COM16.

**<bdaddr>** = the BD address of the target Receiver device. E.g. 11:89:55:45:23:01.

**<.bin file>** = the binary file containing the image.

**<mem\_dev\_opts>** = i2c <i2c\_dev\_opts> | spi <spi\_dev\_opts>

**<i2c\_dev\_opts>** = <image bank> <I2C device addr> <SCL gpio> <SDA gpio> <block size>

**<spi\_dev\_opts>** = <image bank> <MISO gpio> <MOSI gpio> <CS gpio> <SCK gpio> <block size>  
**<image bank>** = the image bank can be 0,1 or 2. "0" means replace the oldest image.  
**<I2C device addr>** = the I2C slave address for the I2C memory device. It is an 8-bit HEX value, e.g. 0B.  
**<XXX gpio>** = the name of the gpio that is assigned for the XXX function, e.g. P2\_2  
**<block size>** = the block size that will be used for the software update over the air procedure. A multiple of 20 is recommended. Block size should not exceed the buffer length of the receiver but should be greater than 64 bytes which is the length of the image header.

Command line examples:

- **SPI:**

```
host_suotai 55 25:07:19:77:99:00 new_firmware.img spi 0 P0_2 P0_3 240
```

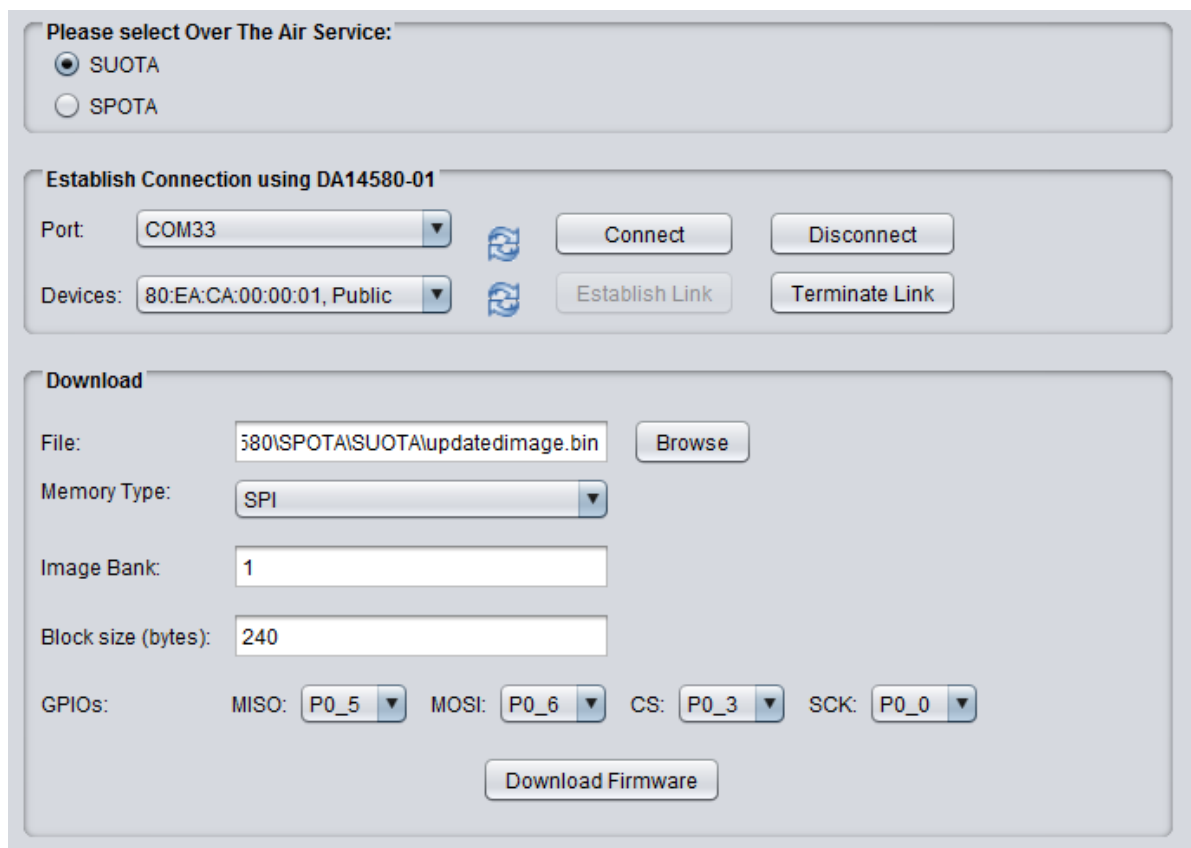

- **I2C:**

```
host_suotai 55 25:07:19:77:99:00 new_firmware.img i2c 0 50 P0_2 P0_3 240
```

### 7.3 Using SmartSnippets as SUOTA Initiator

SmartSnippets toolkit version 3.2 or later can be used as SUOTA Initiator. The toolkit's help menu includes a "User Guide" that provides information of how to configure the Initiator to perform an image update. Figure 6 below illustrates the SUOTA Initiator screen of the SmartSnippets toolkit. This screen is part of the Over The Air services menu of the toolkit.

This application, in conjunction with the DA14580 USB Dongle, implements an external processor solution of SUOTA Initiator. Therefore, to run this application it is assumed that the DA14580 USB Dongle is already installed and can be used by the Windows machine.

**Please select Over The Air Service:**

☒ SUOTA  
☐ SPOTA

---

**Establish Connection using DA14580-01**

Port:  

Devices:  

---

**Download**

File:

Memory Type:

Image Bank:

Block size (bytes):

GPIOs: MISO:  MOSI:  CS:  SCK:

**Figure 6: SmartSnippets SUOTA Initiator configuration options**

Figure 6 shows an example of how one could configure the Initiator to perform an image update:

1. Firstly, choose the Over the Air service (or mode of operation): SUOTA or SPOTA. In this case SUOTA has been selected.
2. Select the com port of the DA14580 USB Dongle that is used as the SUOTA Initiator device. When the dongle is inserted in a Windows machine (e.g. laptop) a J-Link device should be discovered in Windows devices and printers. In J-Link's properties, a JLink CDC UART Port is displayed.
3. Press  to download firmware and connect to DA14580 USB dongle. Upon connection, the Initiator will start to scan for advertising SUOTA Receiver devices.
4. Assuming that the DA14580 SDK is running Proximity Reporter application (note that SUOTA Receiver application is part of Proximity Reporter Integrated processor project), then the Bluetooth address of the Receiver will be discovered and displayed in :  

5. Press  to connect to the Receiver device.
6. After the BLE link has been established, browse to find the image file to be sent to the Receiver.
7. Choose the memory type. Note that image update is only supported for non-volatile memory types of SPI/FLASH and I2C/EEPROM. In this example SPI has been selected.
8. Choose memory bank [8]:

“1” means use the 1<sup>st</sup> bank with start address as indicated in the Product Header

“2” means use the 2<sup>nd</sup> bank with start address as indicated in the Product Header

“0” means burn the image in to the bank that holds the oldest image

9. Choose block size. A few points should be considered when this size is set. Firstly it has to be greater than 64 bytes which is the size of the image header. Secondly, it should be a multiple of 20 bytes which is the maximum amount of data that can be written in SPOTA\_PATCH\_DATA characteristic at once. Lastly, it should not be greater than the SRAM buffer in the Receiver implementation that stores the image data received over BLE link before it burn them to non-volatile memory. A size of 240 bytes is set in this example.

10. Set the GPIO pins of the memory device.

11. Press  to initiate the image update process. It is advisable to look at the log window to detect any error messages that will be displayed in red colour.

## Appendix A Notes to Developers

### A.1 SPOTAR Memory requirements

As explained in [1], patch code is downloaded using the Bluetooth Smart link, and the SPOTAR device can store the patch into the internal RAM or an external non-volatile memory. The software patch is eventually executed as described in [6]. There are of course certain constraints with respect to the physical storage of the patching code. In this appendix, a detailed explanation is given for the implementation of the patch data handling functions so that developers can understand and be able to modify the code according to their needs.

#### Storing patch into Internal RAM

Two memory areas have been reserved in order to handle the software patch data for the Internal RAM implementation:

```
uint8_t spota_new_pd[SPOTA_NEW_PD_SIZE]
__attribute__((section("spotar_patch_area"), zero_init));

uint8_t spota_all_pd[SPOTA_OVERALL_PD_SIZE]
__attribute__((section("spotar_patch_area"), zero_init));
```

SPOTA\_NEW\_PD\_SIZE: Is the size of the maximum individual software patch expected.

SPOTA\_OVERALL\_PD\_SIZE: Is the size of the overall patch space that holds all the individual patches during the lifetime of the device.

It is advised that sleep mode is disabled during software patching in the SPOTAR device. However, if sleep is enabled, then the above memory areas need to be reserved in retention RAM. The following define, in *da14580\_config.h*, determines if these two buffers should be in retention RAM or non-retainable RAM:

```
#ifdef CFG_PRF_SPOTAR
// Placed in the RetRAM when SPOTAR_PATCH_AREA is 0 and in SYSRAM when 1
#define SPOTAR_PATCH_AREA 0
#endif
```

The header file is included in the *scatterfile\_common.sct* where according to the define value the *spotar\_patch\_area* section is reserved in the relevant RAM section. It is important to note that if the SPOTAR project has been compiled with this define set to "1", then the SPOTA\_MEM\_DEV shall not be set to select retention RAM memory device. Equally, if compiled with the define value set to "0", then SPOTA\_MEM\_DEV shall not be set to select RAM memory device. Therefore, the developer should select the right memory area according to his/her needs and configure SPOTAR accordingly. The SPI and the I2C memory devices are not affected by this define.

As seen in paragraph 5, step 5, the patch data are sent in chunks of 20 bytes. SPOTAR device stores these data into *spota\_new\_pd[]* area. When the number of the data received matches the patch length specified by the Initiator, then the CRC is calculated, and if correct, the received patch is stored into *spota\_all\_pd[]* area. This is implemented in function *app\_spotar\_pd\_hdlr()*. Note that the new patch is written into *spota\_all\_pd[]* area starting at the memory location where the old patch(es) end.

**Note 1** If patch data are sent in the reversed order, i.e. least significant word first, then the *spota\_new\_pd[]* is not really required. The new patch data could be copied to the *spota\_all\_pd[]* directly in the order they are received. However, in the case the new patch data has not been received correctly (CRC fails or any other protocol error) then the incomplete patch that has been written to *spota\_all\_pd[]* must be deleted.

**Note 2** CRC calculation is not implemented in the example code. It is left to the developer to choose a CRC method and polynomial length.

#### Storing patch into external non-volatile memory

The same two memory areas are used in this case. As in the case of internal RAM storage, the *spota\_new\_pd[]* is used to store the new patch data as they are received. After the entire new patch has been received successfully, the patch data are written to SPI FLASH or I2C EEPROM

using the functions `spi_flash_write_data()` and `i2c_eeprom_write_data()`, respectively. The example memory access functions are written for the following memory devices:

- SPI flash Winbond W25X10CL
- I2C EEPROM STMicroelectronics M24M01

The `spota_all_pd[]` area is used to store the overall patch when it is fetched in the system RAM from the external non-volatile memory before the patch is executed.

**Note 3** Reserving memory space for the `spota_new_pd[]` can be avoided. New patch data can be stored in to `spota_all_pd[]` and when the entire patch is received successfully it can be written into the external non-volatile memory. However, since the example SPOTAR application supports all memory configurations, the `spota_new_pd[]` is used for code simplicity.

## A.2 Patch Execution

If the software patch has been stored successfully, it will be executed every time the `main_func()` in `arch_main.c` is called (after reset or when system wakes up from deep sleep). In this case, the function `app_spotar_exec_patch()` is called to execute the patch. In the example application code, it can be seen that the function `exec_patching_spota()` is finally called:

```
void exec_patching_spota(WORD mem_dev, WORD gpio_map, WORD* ptr, WORD patch_length)
```

If the SPOTAR device supports more than one memory patch areas, then the `exec_patching_spota()` function shall be called sequentially for every memory area where a patch is stored.

**Note 4** In the example application code, when the `exec_patching_spota()` is called, the GPIO map parameter is hardcoded. The GPIO map characteristic value `SPOTA_GPIO_MAP` cannot be read from the profile data base after reset or after system wake up since it will be uninitialized. However, this should not be a problem considering that the GPIO map of the external non-volatile memory is known for a particular device and it should be fixed.

**Note 5** When running in deep sleep, the patch needs to be executed every time the system wakes up from deep sleep. In this case the patch execution function call needs to be inside the main while(1) loop in `arch_main()`. If the patch has been saved in to an external memory it is very important that the time required for reading the patch from the external memory does not take too long and delays the BLE scheduling. Generally speaking, to be safe, it should finish the patch read and execution before the `BLE_SLP_IRQ` interrupt is triggered.

**Note 6** If we apply the patch in SYSTEM RAM, then the system should never enter deep sleep otherwise the patch data will be lost. In this case, the patch execute function needs to run straight after the patch has been successfully downloaded. An example is provided in demo application and can be found in function `app_spotar_pd_hdlr()`:

```
// Apply patch if SYSRAM has been selected. Can not reset system when patch
// is stored in SYSRAM.
if( (mem_info & 0xffff) > 0)
{
    exec_patching_spota((mem_dev & 0x0000ffff), 0x0, (WORD *) spota_all_pd, (mem_info & 0xffff) );
}
```

## 8 Revision history

Revision	Date	Description
1.0	18-Mar-2014	Initial version.
2.0	23-July-2014	Added SUOTA

**Status definitions**

Status	Definition
DRAFT	The content of this document is under review and subject to formal approval, which may result in modifications or additions.
APPROVED or unmarked	The content of this document has been approved for publication.
